

## Activity 10.1

Reading material on our website on genetic variation in gametes complements each of the following questions. Understanding of the concepts discussed will be assessed.

1. Match each of the following changes in chromosome structure to its definition:

☒ A. Crossing

☐ B. Duplication

☐ C. Inversion

☐ D. Translocation

1a. is fusion of 2 chromosomes by their ends

1b. is presence of chromosome in duplicate

1c. is segment of one chromosome transferred to another chromosome; different, same chromosome, chromosome

1d. is fusion of 2 chromosomes (segment from one moves from one to other)

2. How many genetically different gametes can be produced from a diploid cell with 4 pairs of chromosomes (pairs)? Explain your answer.

There are 16 genetically different gametes that can be produced (using the 2<sup>n</sup> equation to find number chromosomes pairs, 4 chromosomes with 2 pairs chromosomes are 16 possible 2<sup>4</sup> or 16 genetically different gametes)

3. Although you will learn of mechanisms of mutation from genetics, you recognize that some traits carry the less frequent chromosomes (for example, hair color and eye color). Why may some traits be inherited together?

These traits are linked together and travel on the same chromosome. Therefore, they are inherited together as a unit, and a single gene only codes for one trait. Recombinant chromosomes from traits will be found with some frequency in the gametes, usually, depending on how far apart they are.

4. Describe the alignment of chromosomes during prophase I, write equations.

During prophase I, homologous chromosomes align together, called synapsis. This is important because it allows the crossing over to occur and results in new genetic combinations.

5. How does recombination lead to chromosomes with new combinations? Describe two types of genetic mutations that can result from recombination.
