

Selection and Speciation

How can changes in a population result in the formation of a new species?

Why?

Have you ever wondered how the great diversity of life on Earth has come about or how a single new species forms? Environmental pressures may cause populations to change over time or evolve. This is because an organism's ability to live to adulthood in its current environment will determine its reproductive success and ability to pass on its genes. But changes within a population can occur without creating a new species. At what point do scientists start thinking of a new name for a species?

Model 1 – Three Types of Selection

1. What variables do the graphs in Model 1 compare?
2. What are the three types of selection illustrated in the graphs in Model 1?
3. According to the graphs in Model 1, there is variation in the body mass in the original population. Using your knowledge of genetics, describe how this variation is possible.
4. Refer to graph A of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. **Fitness** is defined as the relative ability of an individual (or population) to survive, reproduce, and pass on genes. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph A.
5. Refer to graph B of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph B.
6. Refer to graph C of Model 1.
 - a. How is the population that has experienced selection different from the original population?
 - b. Which individuals in the original population appear to display better fitness?
 - c. As a group, propose some characteristics of the environment that could lead to the population changes illustrated in graph C.

Supporting Teachers' Formative Assessment Practice with Learning Progressions Erin Furtak, 2017-10-05 This book presents the results of a four year National Science Foundation funded project that engaged nine high school biology teachers at three public high schools in long term on site professional development program centered on a learning progression It explores the influence of teacher participation in this professional development experience on their learning about student thinking formative assessment task design classroom practices and student learning Taking an in depth look at the multiple sources of data gathered as part of the study this volume reflects on the emergence of professional communities focused on formative assessment design and enactments and associations between teacher participation in learning progression centered professional development and student learning *The Role of Selection in Speciation* Judith Masters, Selection and Speciation MacDonald, Selection, sex, speciation and species Andrew Cockburn, 1991 *Speciation in Birds* Trevor Price, 2008 In *Speciation in Birds* Trevor Price a University of Chicago professor and leading expert in the field has written the most authoritative and modern synthesis on the subject to date In clear and engaging prose and through beautiful illustrations Price shows us why the field is as exciting and vibrant as ever He evaluates the roles of natural selection and sexual selection He asks how speciation contributes to some of the great patterns in species diversity such as the large number of species in the tropics and the many endemic species on isolated islands Throughout the book Price emphasizes the integration of behavior ecology and genetics Speciation and selection Ernst Mayr, 1949 **On the Origin of Species Through Heteropatric Differentiation** Kevin Winker, 2010-11 Differentiation and speciation without extended isolation appear to be common among migratory animals Historical oversight of this is probably due to temporal distortion in distribution maps and a tendency to consider that lineages had different historical traits such as being sedentary or much less mobile Mobility among cyclic migrants makes population isolation difficult and diminished levels of intraspecific differentiation occur in avian migrants I term this Montgomery s rule Nevertheless many lineages have differentiated despite increased mobility and a high propensity for gene flow conditions that speciation theory has not addressed adequately Populations of seasonal migrants usually occur in allopatry and sympatry during a migratory cycle and this distributional pattern heteropatry is the focus of a model empirically developed to explain differentiation in migratory lineages Divergence arises through disruptive selection from resource competition and heterogeneously distributed cyclic resources Heteropatric speciation is a type of ecological speciation in which reproductive isolation increases between populations as a byproduct of adaptation to different environments that enhances breeding allopatry and allochrony despite degrees of sympatry that occur during the nonbreeding period in migration cycles Mating or pair bonding in nonbreeding areas is rare Patterns such as leapfrog migration and limited morphological divergence suggest that differentiation is driven by these ecological factors rather than by sexual selection or nontemporal changes in the resource base itself although the additional presence of either

of the latter would have additive divergent effects Migratory lineages provide a largely neglected series of natural experiments in speciation in which to test predictions stemming from this model and others focusing on ecological speciation

Genetics of Speciation David L. Jameson, 1977 **Speciation and the Recognition Concept** David M. Lambert, Hamish G. Spencer, 1995 Developed by Hugh E. H. Paterson in the 1970s the Recognition Concept of Species stressed the importance of the Specific Mate Recognition System (SMRS) and offered a view of species which was radically different from the traditional Isolation Concept. Paterson held that new species were formed through incidental changes in the SMRS rather than being directly promoted. In the two decades since Paterson first advanced his theory evolutionary biologists around the world have had the opportunity to use this approach in their work. **Speciation and the Recognition Concept** is the first book to bring together a group of leading researchers to examine the relevance of Paterson's ideas today for this important topic in evolutionary biology. Representing a wide variety of viewpoints the contributors explore the consequences of applying the concept to areas as diverse as the fossil record, insect taxonomy, the structure of mate recognition systems, speciation models, and the concept function in biology. The Recognition Concept of species, write the editors, is important to biology because it represents an innovative approach to the resolution of the problem of biological diversity. The concept is based upon an analysis of the logic and language of species studies. Consequently it offers significant implications for ideas about the origin of species.

The Interaction Between Natural and Sexual Selection and the Maintenance of Biological Diversity Amy K. Schwartz, 2009

Repeated Trait Evolution Driven by Divergent Natural Selection at Early and Late Stages of Speciation Spencer J. Ingle, 2015 Speciation, the process by which new species arise, is of fundamental importance in the biological sciences. The means by which new species arise and the relationship among living species has been a topic that has captivated both lay and scientific observers for centuries. In recent years the study of speciation has enjoyed increased attention, resulting in significant advances in our understanding of how species form. Although our understanding of the processes that contribute to speciation has increased dramatically in recent years, our knowledge of how reproductive barriers accumulate as speciation proceeds is still limited. Thus studies that evaluate trait divergence and its consequences at early versus late stages of divergence can provide valuable insight into the speciation process. Chapter 1 of my dissertation focuses on the role of animal personality in the speciation process. Animal personality, defined as consistent individual differences in behavioral tendencies, has been identified as a key player in several ecological and evolutionary processes, yet the role of personality in speciation remains unexplored. In this chapter I discuss the ways by which personality can contribute to a suite of reproductive barriers and drive the speciation process. Chapters 2 through 5 provide a case study evaluating how selection acts on traits at early and late stages of speciation using the Neotropical livebearing fish genus *Brachyrhaphis* as a model system. *Brachyrhaphis* is ideally suited for this research because several species pairs and population pairs within species occur in similarly divergent selective regimes. I first present

results from a field demographic study that shows that the strength of divergent selection acting on life history traits in populations from divergent predation environments diminishes as speciation proceeds I then show that population pairs at different stages of divergence are evolving similar morphological patterns along parallel trajectories At both early and late stages of divergence populations from environments with dense predator populations have a body shape that appears to be optimized for burst speed swimming and important component of predator escape In contrast populations from environments lacking predators have a body shape optimized for endurance swimming ability which is important in environments where competition for foods and mates is high Next I show that populations from divergent predation environments do indeed differ in their swimming abilities according to our predictions reflecting a population level trade off between burst and endurance swimming ability Although population level trade offs were strong I found no evidence of within population level trade offs suggesting that populations have arrived at novel solutions to between population trade offs that were not present within ancestral populations Finally I show that these specialized swimming modes are locally adaptive and that divergent ecology selects against immigrants effectively reducing gene flow between populations from divergent environments Together these studies provide a valuable glimpse into the repeatability and predictability of trait divergence at different stages of speciation

Geographic Variation, Speciation and Clines John A. Endler, 2020-03-31 Geographic Variation Speciation and Clines explores the origins and development of geographic variation divergence and speciation In particular it is concerned with genetic divergence as it is usually found on continents among groups of populations isolated only by distance Although earlier writers on this topic considered the effects of geography and dispersal intense geographic differentiation and speciation were thought to require complete isolation Professor Endler shows how geographic differentiation and speciation may develop in spite of continuous gene flow Following a review of the diverse and scattered literature on gene flow and population differentiation the author discusses the relationships among gene flow dispersal and migration He then summarizes the factors which limit the geographic extent of gene flow and those which allow steep clines to develop in the absence of barriers to gene flow His analysis draws on examples from the field experiments and single and multiple locus models The mechanism and conditions for parapatric speciation are presented steepening clines development into hybrid zones and the evolution of sexual isolation In the final chapter the author considers the interpretation of natural clines and the associated geographic patterns of subspecies and species

H. Lowe-McConnell,Ro McConnell,1969 Color Variation and Its Role in Speciation Florine Pascal,2022

The study of intraspecific contact zones can provide important insights into the processes that underlie lineage divergence and potentially mediate speciation Contact zones frequently exhibit some level of hybridization among lineages with the consequences of hybridization on speciation depending in part on the strength of selection Here we focused on a red eyed treefrog *Agalychnis callidryas* contact zone *Agalychnis callidryas* is a brightly colored and polymorphic frog with a broad distribution throughout Central America Populations differ greatly in leg color stripe pattern size call and skin peptide composition but most populations in Costa Rica and Panama exhibit relatively little variation in phenotype Females the choosier sex prefer males from their own population indicating a role of premating reproductive isolation on lineage divergence Previously our lab identified a contact zone between two *A callidryas* lineages consisting of multiple phenotypes and late generation hybrids Here we characterize the phenotypes from five populations along this contact zone focusing primarily on leg color and stripe type We then use the quantification of color pattern variation to identify evidence of naturally occurring mate choice We found complex continuous color variation along the contact zone and evidence of assortative mating in the parental population but random mating in the contact zone We found evidence of directional selection in both parental and contact zone populations Combined these data assess the potential for lineage divergence between the two parent populations in this dynamic system
