ABSTRACT

There are many applications which based on Microcontroller. They are user friendly and capable of interacting with the external peripherals. To accomplish these tasks, a microcontroller device has digital inputs/outputs, pulsed inputs/outputs analog inputs/outputs, etc. There are serial and parallel data communications which are used in data communication. Parallel communication required more number of wires, and can communicate more number of bits at a time whereas Serial communication has gained more importance now-a-day. This is more appropriate to discuss some more PIC functions that can support the above mentioned requirements. Another requirement is External events and their occurrence at the exact point of time and generation of precise timing at the output pins of the microcontroller on a real time. There are two CCP modules in 16F877 supporting capture/compare and PWM functions discuss in present paper. This module allows detecting exact timing of the occurrence of an event or can generate exact timing at the output.

Keywords: PIC 16F877, CCP1, CCP2, PWM

I. INTRODUCTION

Microcontroller-based designs are very flexible and compact. Use of supporting integrated circuits for interfacing sensors and transducers makes the design very simple and cost effective. Use of serial ADC, SPI and I²C bus interface can save the number of microcontroller pins.

Measurement of physical quantities is an integral part of any engineering application. Various sensors are used to extract the information from a physical media and this information is then converted into suitable form.

Transmission of this information to a remote place is a need where it is monitored and used to take certain action. The role of microcontrollers must be very clear in all these systems. Earlier measurement systems used to have analog circuits for signal conditioning. However, due to digital processing of signals, today it is possible to carry out more complex functions in a better manner and then communicate this information more precisely to the display or controlling device. Two-way communication among various instruments is possible due to the built-in facilities of serial communication in microcontrollers. Newer design of signal transmitters, converters and controllers use digital processing of signals. Use of microcontroller-based instruments makes the system more reliable, flexible and powerful with many more facilities to fulfill the needs of control systems.

II. CAPTURE/COMPARE/PWM (CCP) MODULES IN PIC 16F877

A Capture/Compare/PWM (CCP) module supports the measurement, control and the generation of pulsed signals with respect to time precisely. In capture mode, it is possible to transfer the contents of an internal 16-bit timer into a special function register, upon detection of a rising or falling edge. The compare mode generates an interrupt, or changes the status of an output pin, when timer 1 matches a predefined comparison value.

Pulse Width modulation (PWM) mode allows generating a rectangular wave with programmable duty cycle at the user set frequency. There are two CCP modules in PIC 16F877, namely, CCP1 and CCP2. Both have almost similar operations in supporting capture, compare and PWM functions. Each of the CCP modules has a 16-bit capture register, a 16-bit compare register and a PWM
