

thinking: If the rate of release of  $\text{CO}_2$  from the biota was growing at an identical rate to the  $\text{CO}_2$  release from fossil fuels, we would find it hard to detect; and if the biotic release was matched by some unknown  $\text{CO}_2$  sink, the releases could indeed be large. So far we cannot unequivocally support either of these scenarios.

In summary, the recent estimates of an atmospheric  $\text{CO}_2$  concentration of about 265 ppm around 1850 lead to a predicted warming greater than that yet observed today if we use the upper range of climate model results, and point to a net  $\text{CO}_2$  source from the terrestrial biosphere contributing about 25 ppm to the atmospheric levels. This flux from the biota most likely occurred in the late nineteenth century and early decades of this century. The net release from the biosphere today could be about 2 Gt of C per year, although lesser or negative fluxes would not be inconsistent with oceanic and atmospheric models. Finally, we must keep in mind, as Revelle's analysis (Section 3.5) of methane hydrates in continental slope sediments suggests, that climate change may bring about surprising changes in fluxes of carbon.

### 3.2 CARBON DIOXIDE AND THE OCEANS

*Peter G. Brewer*

The effect of solution of the gas by the sea water was next considered, because the sea acts as a giant regulator of carbon dioxide and holds some sixty times as much as the atmosphere. The rate at which the sea water could correct an excess of atmospheric carbon dioxide depends mainly upon the fresh volume of water exposed to the air each year, because equilibrium with the atmospheric gases is only established to a depth of about 200 m during such a period. The vertical circulation of the oceans is not well understood, but several factors point to an equilibrium time, in which the whole sea volume is exposed to the atmosphere of between two and five thousand years.

--Callendar (1938)

#### 3.2.1 Introduction

The quotation above is still, after more than 40 years of progress, as succinct a statement of the problem as one could desire. The rising atmospheric  $\text{CO}_2$  level has been carefully measured since 1958. Calculations made on the amount of fossil fuel  $\text{CO}_2$  released during this time, based on good records of oil, coal, and gas combustion, show that the observed increase in atmospheric  $\text{CO}_2$  is a little more than half the amount of fossil fuel  $\text{CO}_2$  input.
