10. Photosynthesis begins when light (energy) strikes photosynthesizing chloroplasts, breaking bonds that connect their molecules.

11. ATP consists of adenine, a 5-carbon sugar called ribose, and three phosphate groups. Within the bonds between the second and third phosphate groups, energy is released.

12. ATP can be compared to a fully-charged battery because both ATP and NADPH contain stored energy. When ATP encounters a molecule charged battery, however, it tends to use that energy, it has an additional "charge" or glucose.

13. ATP is used as immediate energy and is very short lived and glucose is used as a storage and can be converted into ATP molecules later.

14. Glucose, obtained from plants without oxygen, which can later be used for energy. Spontaneous reactions that produce most sunlight to produce oxygen. Most of them the water-splitting, releasing-releasing oxygen.

15. $6H_2O + 6CO_2 \rightarrow C_6H_{12}O_6 + 6O_2$ (just light & chlorophyll & water)

without glucose & water & oxygen & oxygen

16. In addition to water and carbon dioxide, photosynthesis requires light and chlorophyll. These systems that use light energy with light-absorbing molecules called pigments. The most common pigment is chlorophyll. There are two main types of chlorophyll: chlorophyll a and chlorophyll b.

17. In the chloroplast, it is the stroma, the region outside the thylakoid membranes. It is a glucose, a series of thylakoids. It is a photosynthetic, a series of pigments and proteins that absorb light energy and is located within chloroplasts membrane called thylakoids. The thylakoid stacks are called grana.

18. NADPH (nicotinamide adenine dinucleotide phosphate) accept and donate a high-energy electron along with a hydrogen ion. This converts the NADP+ into NADPH. The conversion of NADP+ into NADPH is used only to absorb some of the energy of sunlight and for production chemical bond. The NADPH can then use high-energy electrons produced by light absorption in chloroplast membrane structures in the cell. These high-energy electrons build a series of molecules that will result, including carbohydrates that glucose.

19. Hydrogen ions are used to power the synthesis of ATP. The cell membrane contains a protein called ATP synthase that uses the membrane and allows hydrogen ions to pass through it. The hydrogen ions pass through ATP synthase, the protein channel like a turbine being spun by water.
