Solutions to Review Questions - Chapter 5

1. In the same way as we make assumptions about the true value of beta and not the estimated values, we make assumptions about the true unobservable disturbance terms rather than their estimated counterparts, the residuals.

We know the exact value of the residuals, since they are defined by $\hat{u}_t = y_t - \hat{y}_t$. So we do not need to make any assumptions about the residuals since we already know their value. We make assumptions about the unobservable error terms since it is always the true value of the population disturbances that we are really interested in, although we never actually know what these are.

2. We would like to see no pattern in the residual plot! If there is a pattern in the residual plot, this is an indication that there is still some "action" or variability left in y_t that has not been explained by our model. This indicates that potentially it may be possible to form a better model, perhaps using additional or completely different explanatory variables, or by using lags of either the dependent or of one or more of the explanatory variables. Recall that the two plots shown on pages 157 and 159, where the residuals followed a cyclical pattern, and when they followed an alternating pattern are used as indications that the residuals are positively and negatively autocorrelated respectively.

Another problem if there is a "pattern" in the residuals is that, if it does indicate the presence of autocorrelation, then this may suggest that our standard error estimates for the coefficients could be wrong and hence any inferences we make about the coefficients could be misleading.

3. The t-ratios for the coefficients in this model are given in the third row after the standard errors. They are calculated by dividing the individual coefficients by their standard errors.

$$\begin{array}{lcl} \hat{y}_t = & 0.638 & + 0.402 x_{2t} - 0.891 x_{3t} \quad R^2 = 0.96, \bar{R}^2 = 0.89 \\ & (0.436) & (0.291) \quad (0.763) \\ \text{t-ratios} & 1.46 & \quad 1.38 \quad -1.17 \end{array}$$

The problem appears to be that the regression parameters are all individually insignificant (i.e. not significantly different from zero), although the value of R^2 and its

Features and capabilities of the REG, ANOVA and GLM procedures are included in this introduction to analysing linear models with the SAS System. This guide shows how to apply the appropriate procedure to data analysis problems and understand PROC GLM output. Other helpful guidelines and discussions cover the following significant areas: Multivariate linear models, lack of fit analysis, covariance and heterogeneity of slopes, a classification with both crossed and nested effects and analysis of variance for balanced data. This fourth edition includes updated examples, new software related features and new material, including a chapter on generalised linear models. Version 8 of the SAS System was used to run the SAS code examples in the book. Provides clear explanations of how to use SAS to analyse linear models. Includes numerous SAS outputs. Includes new chapter on generalised linear models. Uses version 8 of the SAS system. This book assists data analysts who use SAS/STAT software to analyse data using regression analysis and

analysis of variance It assumes familiarity with basic SAS concepts such as creating SAS data sets with the DATA step and manipulating SAS data sets with the procedures in base SAS software
